THE AGROECOLOGICAL OPIUM OF THE MASSES

by Jim Chen

The history of all hitherto existing agriculture is the history of industrialization. Four decades after the term “agribusiness” entered the American language, we can no longer deny the irreversible industrialization of food production in the United States. The only question left is whether this transformation of agriculture bodes ill or well for the environment.

But a specter is haunting American agriculture, the specter of agroecological ideology.¹ “Sustainable agriculture” is on the verge of political capture, of being corrupted into the most recent variant of “agricultural fundamentalism.” At their height, the fundamentalist preachers of agrarian supremacy defended price and income support for farmers by arguing that every dollar of gross farm income generated seven dollars of national income. Today, concerns over “farm size” motivate the self-described sustainability advocates who argue that “the goal of sustainable agriculture programs should be to serve small or family farmers instead of large corporate farms.”² Under a strict definition of sustainability, however, “[s]ustainable agriculture consists” simply of “processes involving biological activities of growth or reproduction intended to produce crops, which do not undermine our future capacity to successfully practice agriculture” and which do not “exhaust any irreplaceable resources which are essential to agriculture.”³

The quest for sustainability has therefore reached a crucial moment of truth. Will the drive for sustainability remain true to alternative agriculture’s “urgent concern over the ecological aspects of agriculture,” or will it dissolve into nothing more than “the latest manifestation of the ongoing struggle between agrarianism and industrial concentration,” yet another debate over the economic characteristics of individual farms, the distribution of productive assets in agriculture, and the number of managerial job opportunities in farming?⁴

Most rhetorical questions come prepackaged with rhetorical answers, and mine is no exception: Environmental integrity can occur in a corporate envi-

ronment. Witness the use of organic viticultural techniques by Gallo Brothers and the practice of integrated pest management by the Mall of America. To assert otherwise is to make environmentalism contingent upon the pecuniary preferences of environmentalists.

Unless we can decouple the notion of sustainability from issues of farm income and economic viability in agriculture, the sustainable agriculture movement will have accomplished little more than the greatest rhetorical coup since certain partisans in the American debate over abortion fashioned the phrase “pro-life.” There are now as many self-described champions of “unsustainable agriculture” as there are overt supporters of the “pro-death” crusade. Unless we expect to feed ourselves on rhetoric alone, however, we must define exactly what it means to “sustain” agricultural production.

Virtually every adherent of the agroecological ideology emphasizes the land on which we farm, the land that feeds us. Thus contemporary admirers of Aldo Leopold celebrate the gift of good land and solemnly admonish us all that our patterns of consumption must meet the expectations of the land. The new environmental awareness supposedly marks an intellectual shift from a mechanical model of agriculture to an ecological model. All of this rhetoric would be far more credible if the agroecological agenda did not so transparently disguise a willingness to sacrifice environmental objectives whenever they conflict with the greater interest in protecting incumbent farmers at all costs.

Das hormon: the hormone wars

The reaction to the latest agricultural innovation to alter the American dairy market, recombinant somatotropin (rbST), confirms the true nature of support for environment-enhancing developments in contemporary agriculture. Recombinant somatotropin—or recombinant bovine growth hormone (rBGH), as the drug’s opponents prefer to call it—represents a rather modest biotechnological advance. Because it is merely the synthetic form of a natu-

rally occurring hormone that stimulates milk production, the creation of rbST is a rather crude extension of the scientific revolution launched by Friedrich Wöhler's synthesis of urea from ammonium cyanate in 1828. In 1937, Russian scientists correctly hypothesized that some chemical produced by the anterior pituitary gland controlled bovine lactation. American scientists eventually concluded that bST governed the efficiency with which cows absorbed nutrients and thereby produced milk. By extracting bST-stimulating genes from bovine pituitary glands and splicing them into rapidly reproducing *E. coli* bacteria, bioengineers have facilitated the large-scale, economically feasible synthesis of rbST. In 1982, the first trials demonstrated that recombinant bST could be used to boost milk production in a safe, cost-effective fashion.

Recombinant somatotropin did not ambush the American dairy industry. The product's entry into the market was long expected; threatened dairy farmers had ample time to adjust to a market that would inevitably change. No other recent legal event in American agriculture, however, has provoked as much agrarian anger as the Food and Drug Administration's (FDA) decision to permit the use of rbST in milk production.

Fully expecting the FDA to approve rbST sometime in late 1993, Congress preemptively imposed a ninety-day moratorium on rbST sales after the date of any such approval. A concurrent ninety-day delay in an otherwise scheduled reduction in federal milk price supports cost taxpayers an additional \$5 million in milk subsidies. Given the extraordinarily income-inelastic nature of milk demand, Congress's resistance to the expected decrease

in milk prices disproportionately hurt the poorest, youngest consumers of milk.

Legislators representing Wisconsin and Vermont—two states whose dairy farmers expected to lose the most from widespread adoption of rbST—proposed even more ambitious legislation to extend the rbST moratorium, to require the labeling of milk and milk products from rbST-treated cows, and to reduce price support for dairy producers who inject rbST into their cows. Several states, especially in New England and the Upper Midwest, have authorized voluntary labeling schemes. A few have even considered mandatory labeling statutes. Throughout the spring and summer of 1994, legislative activity was so intense that several agricultural interest groups were able to report "rBGH news of the week."

Currently, American agricultural policy regarding rbST use takes the form of piecemeal second-guessing by state legislatures of a scientific judgment made by the FDA as the United States's legally designated, nationwide expert agency on food and drug safety. Before assessing whether the risks to human health can justify such a violent regulatory reaction to rbST, I am prepared to eliminate animal health for its own sake from the list of substantial concerns. To the extent that rbST impairs treated cows' reproductive performance or "adversely affect[s] the processing characteristics of milk," economically rational farmers will weigh the technology's benefits against its fully internalized costs.⁵ Moreover, the very business of dairy production is fundamentally incompatible with the notion of animal rights. Milk is meat, for every dairy cow put into production bears calves des-

trained to become veal. Every cow eventually becomes a mound of ground beef. *Homo sapiens* does not build cemeteries for pet dairy cattle. Perhaps she should, but she does not.

No, something else is at work. The pungent odor of producer protectionism permeates the legislative air.

Recombinant somatotropin does not endanger human health. Cow's milk naturally contains bo-

Stripped of its fraudulent claims to ethical and medical integrity, the campaign against rbST is a battle waged by economically endangered entities against the rest of society.

vine somatotropin. There is no significant compositional difference between Milk Classic from untreated cows and New Milk from treated cows. The presence of a few extra amino acids on the end of the recombinant bST molecule has no impact on the hormone's biological activity. Thanks to the hormone's unique three-dimensional shape, neither natural nor synthetic bST can bind itself to human cell surfaces. Although the Office of Technology Assessment initially thought that rbST use boosts levels of insulin-like growth factor 1 (IGF-1) in milk, more recent studies by the FDA and the Food and Agricultural Organization of the United Nations have concluded that rbST supplementation of cows does not affect the IGF-1 content of milk. In any event, the total amount of IGF-1 in a liter of milk approximates the amount in the saliva swallowed daily by an adult. Accordingly, any IGF-1 that enters the bloodstream after digestion "is insignificant compared to the daily endogenous human exposure."⁶

Recombinant somatotropin's opponents have also argued that the hormone poses an indirect threat to human health by increasing the incidence of mastitis in treated cows, which would lead to increased use of antibiotics by dairy farmers. (Never mind the mountain of scientific data showing "that treatment with BST [has] had no effects of biological importance on mastitis-related variables.")⁷ The agrarians have never explained why stringent enforcement of rules against marketing milk from diseased cows would fail to address any mastitis problem that did exist. Nor have rbST's opponents explained why Congress and state legislatures should be content merely to label a product that poses such a dire threat to the public health. One member of Congress who opposed the rbST approval inadvertently stated his constituents' true priorities

on this issue: "BGH not only threatens the survival of the family farm—it also is a threat to public health." Farmers come first; consumers are, at best, an afterthought.⁸

The political circus surrounding the approval of rbST has obscured the drug's potentially beneficial environmental impact. The misleading description of rbST's sole purpose as "enhanc[ing] the production of a product that is already in surplus"⁹ detracts attention from the commodity that is truly in surplus: dairy cows. By increasing each cow's milk output in a market where demand for milk will likely remain relatively constant, rbST reduces the total number of cows in production. Although a treated cow's greater milk output increases her total energy requirement, rbST improves the cow's efficiency in converting nutrients to milk and reduces the amount of nutrition needed to keep the cow alive.¹⁰

In other words, treating cows with rbST buys more milk production without proportionally increasing the bovine demand for scarce and environmentally costly nutrients. Put plainly, rbST and other advanced dairy technologies "allow for the production of milk with a lower resource input."¹¹ Fewer cows mean fewer methane emissions, less manure, less acreage dedicated to feed for dairy cows, less water committed to the quenching of bovine thirst. Recombinant somatotropin's "green" effect foreshadows the promise of genetically engineered, pest-resistant plant varieties that will reduce farmers' reliance on chemical pesticides.¹²

Throughout the rbST debate, one might have expected genuine protectors of the environment to consider the relationship between productivity and environmental impact. A single set of ecological formulae—hundredweights of milk per kilogram of manure, per liter of urine, per cubic meter of methane—would have illuminated the potential environmental impact of widespread hormone use in the U.S. dairy industry. Such analysis does exist—within the work of dairy scientists whose work made rbST a practical reality. At no time have enemies of rbST, *especially* those who justified their opposition on agroecological grounds, even examined this issue.

According to Dale E. Bauman, one of America's foremost dairy scientists, rbST adoption by the entire American dairy industry would help the environment by effecting the following annual reductions in inputs and waste products:

Inputs:

- The food energy contained in 2.5 billion kilograms of corn
- The protein contained in 56 million kilograms of soybean oil meal

Waste products:

- 6 billion kilograms of bovine manure
- 8 billion liters of bovine urine
- 80 million kilograms of urinary nitrogen
- 80 billion liters of methane

If every American dairy farmer deployed rbST, the industry's reduced demand for feed would equal 0.62 percent of the corn that Americans fed to farm animals in 1988. America's population of dairy cows, 10 million strong in 1988, would also decline by more than a tenth. Imagine the potential environmental benefits of being able to quench America's thirst for milk with a million fewer cows.¹³

But fewer dairy cows also mean fewer dairy farmers. "With each cow producing more milk, the nation's milk needs can be supplied with fewer cows, less land, and fewer people in the dairy industry."¹⁴ Furthermore, reducing the number of cows per farm increases each farm's relative investment in nonbiological inputs. Under a set of more sanguine economic assumptions, of course, on-farm employment prospects might actually improve; a rapidly modernizing dairy industry may demand a generation of on-site managers with greater technological proficiency. Even so, let us assume the worst. Softening the harsh environmental impact of dairy production through Monsanto's meek drug will come at the expense of a few dairy farming jobs. Confronted with a choice between a cleaner environment and reduced employment prospects for incumbent dairy farmers, the agroecological ideologues have unequivocally sided with the farmers.

Regardless of the outcome of today's milk wars, the biotechnological revolution in dairy production will surely continue. Already, bioengineers have successfully used nuclear transplantation to clone transgenic calves.¹⁵ Although "the lack of knowledge about the relationship between the expression of a specific gene and the physiological consequences" of that gene currently blocks the production of "transgenic cattle possessing traits of economic value,"¹⁶ cows that have been transgenically altered to produce high levels of natural bST could eventually supplant rbST use altogether. Barring changes to current law, bioengineered Bossie will surely be patentable. The potential shock to the farm economy will undoubtedly draw Congress even further into the battle over biotechnology.

O brave moo world, that has such creatures in it!

The tempest over rbST represents an ill omen of things yet to come, the harbinger of a far greater war against consumer welfare and environmental integrity. An overwhelming body of scientific evidence attests to the safety of rbST use. The prospect of reducing environmental damage while continuing to satisfy the public's demand for milk

would tantalize any genuine friend of Mother Earth. Every legislative proposal to limit the hormone's use therefore has a normatively pernicious objective: permitting a subclass of Luddite farmers in the United States to continue resisting cost-reducing, resource-conserving technology simply for tradition's sake. Stripped of its fraudulent claims to ethical and medical integrity, the campaign against rbST is a battle waged by economically endangered entities against the rest of society.

The consumerist manifesto

Seduced by an agrarian literary tradition stretching from Little Bo Peep to Little House on the Prairie, we Americans have forgotten an ugly but essential truth about production agriculture: farming is not an environmentally benign activity. Compelling the

earth to yield only such fruits as will sate human hunger and slake human thirst necessarily upsets the balance of nature. In one of the richest ironies in this enigmatic corner of American law and politics, the same farmers who opportunistically designate themselves the divinely foreordained stewards of the land! ordinarily frame the legal "right to farm" as a blanket exemption from nuisance law, a mild and basic common law tool for protecting the public against environmentally destructive uses of land. In each of the fifty states that exempt farmers from liability for their nuisances, agricultural pollution that limits every other conceivable use of increasingly scarce land is tolerated as the sacrosanct foundation of the "right to farm."

Thanks in part to a Western moral heritage "that

views material concern as a defect in human nature," we Americans have slipped into "a romantic view of man's relationship to the natural world."¹⁸ Having forgotten that ours is a "fallen world,"¹⁹ we have swallowed the fallacy "that technology alienates man from both the natural world and from

Agriculture remains the only major industry for which the leading policy prescription consists of reflexive resistance to technological evolution.

the natural community."²⁰ Perhaps we should ask "the Taiwanese farmer [who] harvests a yield of 6 tonnes of rice from his 1 hectare" by using advanced agricultural technology whether he "feels a greater alienation than his father who realized less than 2 tonnes of rice from his efforts."²¹ In the harshly competitive markets of the twenty-first century, the United States cannot afford an ideology that condemns "continued declines in the real costs of production."²² Nor can the rest of the world, not when unprecedented rates of population growth outstrip the productive capacity of traditional agricultural systems.

Don Paarlberg once wrote that "the most important event that has happened in agriculture during [his] lifetime" was agriculture's loss of "uniqueness." In this one instance, and perhaps only in one sense, Paarlberg is dead wrong. Agriculture remains the only major industry for which the leading policy prescription consists of reflexive resistance to technological evolution. Agriculture alone vilifies its own scientists, turning them from the "true revolutionaries of the twentieth century" and "the liberat[ors] of man from the limitations of the natural world"²³ into the serpents of the agroecological paradise. Among the numerous industries that convert natural resources for human consumption, only agriculture claims that it positively transforms the environment.²⁴ Is it any wonder that the agricultural policy of the world's most productive agricultural nation "has focused" almost exclusively "on losers"?²⁵

Agrarian tradition routinely describes farming as a labor of love. It may be impossible to contest this proposition without smelling the stench of cow manure every minute of the waking day, without walking in trousers drenched with the blood of slaughtered hogs. But this much is within the reach of any urbanite willing to overcome the dual handicap of agricultural illiteracy and bucolic sentimentalism: the agrarian dogma of producer primacy

rests solely on a love of labor. American agriculture's commitment to distributive justice will appear far more sincere when its advocates treat consumer welfare as a legitimate component of societal interest in agriculture and not as an inconvenient detail in a futile campaign to maximize demand for the labor of the farm sector's entrepreneurial class.

Consumers of the world, unite. You have nothing to lose but your bucolic illusions. You have a world to win. ■

The author wishes to thank Dale E. Bauman for his especially thoughtful insights on dairy science, Vernon W. Ruttan for invaluable discussions of agricultural economics and the political economy of American agriculture, and Deanna Johnson for providing capable research assistance.

The legal and economic arguments underlying this paper are more fully developed in Professor Chen's article, "The American Ideology," published in the Vanderbilt Law Review (Vol. 48, May 1995, pp. 809-77).
